

Enhancement of Cold Water Sources for Salmon Refuge in the lower Columbia River Gorge: 3D Modeling Assessment

Background

- Year 3 of an ongoing, EPA-funded study of cold water inputs to the lower Columbia River
- Year 1: Lower Gorge tributary assessment (15 streams) (water temperature, plume formation, flow)
- Year 2: Main-stem and downstream tributary assessment

Lower Columbia River Thermal Refuge Study, 2015–2018

Report of research by

Lower Columbia Estuary Partnership
811 SW Naito Parkway, Suite 410
Portland, Oregon 97204

for

United States Environmental Protection Agency

June 2018

Rationale for study

- Warming main-stem temperatures associated with climate change
- Few existing, suitable thermal refuge areas in lower Columbia R.
- Extensive salmon use of man-made, cold water embayments at mid-Columbia tributary confluences:

Herman Creek

Eagle Creek

Drano Lake

Question

Can we alter the hydrodynamics around lower Gorge tributary confluences to create suitable refuges for summer migrating salmon, similar to those found upstream?

Future aspects:
cost,
geomorphic analysis,
social considerations

Photo courtesy of Tony Meyer, LCFEC

Challenges

Gorge streams have lower flows relative to mid-Columbia refuge tributaries

Lack of natural or manmade enclosures surrounding Gorge stream confluences

Mid Columbia Tribs.

Little White Salmon R. ~ 90 cfs

Drano Lake: ~ 800k m²

Google Earth

Lower Gorge Tribs.

Mult./Wahkeena Cr. ~ 8 cfs

Google Earth

Herman Cr. ~ 25 cfs

~ 80k m²

Google Earth

Horsetail/Oneonta Cr. ~ 4 cfs

Google Earth

Approach

Use 3D hydrodynamic model with water temperature module to model:

- existing conditions
- multiple stream outlet/flow diversion structure orientations

- include atmospheric effects (radiation, air temperature, clouds, precipitation, wind)

Tributary Selection

cold, adequate discharge, accessible to adult/juvenile salmonids

| | Bridal Veil Cr. | Multnomah/Wahkeena Cr. | Horsetail Oneonta Cr. |
|------------------|-----------------|------------------------|-----------------------|
| flow (cfs) | 14 – 10 | 11 – 7 | 7 – 3 |
| temperature (°C) | 13.5 (mean) | 13.3 (mean) | 17.2 (mean) |
| juvenile access | Yes | Yes | Yes |
| adult access | ?? | Yes | Yes |

Relevant depth contours for salmon migration:

0.5 m (juvenile) 2m depth (adult) 10m depth (adult)

- WSEmax - - - WSEmax - - - WSEmax
- WSEmin — WSEmin — WSEmin

Derivation of 0.5 m depth contours for Bridal Veil Creek

0.5m depth contour @ max. WSE (dim A): 4.4 - 0.5 = 3.9 m elev. contour
 0.5m depth contour @ min. WSE (dim B): 3.3 - 0.5 = 2.8 m elev. contour

Water temperatures, selected tributaries

Physical Model

Atmospheric inputs applied globally:

- solar radiation
- air temperature, relative humidity
- cloud cover
- precipitation
- wind

Model Boundary Data Selection

- Period of interest for salmonids: July – August
- Available forcing data:
 - **2008** water surface elev. data at Sand Island (downstream boundary)
 - 2008 is a good representation of average conditions:

Daily discharge @ Bonneville vs. 1990-2017 % exceedance

Model Boundary Data Selection

- WSE comparison, 2008 vs. average:

Daily WSE below Bonneville for summer period of interest

Model Boundary Inputs

Sample time period:

| | Columbia R. | | Tributary Q | | | Water temp. | | | | Atmospheric Inputs | | | | | | | |
|--------------|-------------|----------|-------------|----------|-----------|-------------|------|------|------|--------------------|-------|--------|--------|---------|--------|-----|----|
| time | WL (m) | Q (kcfs) | Qbv (cfs) | Qm (cfs) | Qht (cfs) | Tcol | Tbv | Tm | Tht | AIR_TEMP | CLOUD | LW_RAD | PRECIP | REL_HUM | SW_RAD | Wx | Wy |

spatial temperature differences over time between scenarios

US structure – existing condition (at max. depth):

blue shades: areas of cold water enhancement

Results - Horsetail Creek

- Plume characteristics are dynamic

water temperature @ plume center, 3 scenarios

- Relative contributions from:
 - Columbia River forcing (discharge and temperature)
 - atmospheric forcing (temperature, clouds, rain, wind)

Results - Horsetail Creek

Does DS structure enhance plume? Maybe, if wind is factored in:

water temperature for US+DS scenario with varied wind

- 0 wind applied
- true wind applied
- 2x true wind applied
- true wind speed

Largest differences during late day (maximum wind velocities)
Stronger west winds enhance plume? Needs more analysis..

Relative Plume Size Comparison

- mid - Columbia refuges:
 - Eagle Creek: $\sim 5,000 \text{ m}^2$
 - Herman Creek: $\sim 80,000 \text{ m}^2$
 - lower Columbia modeled *initial plume estimates:
 - Horsetail Creek: $\sim 5,000 \text{ m}^2$
 - Multnomah Creek: $\sim 25,000 \text{ m}^2$
 - Bridal Veil Creek: $\sim 20,000 - 30,000 \text{ m}^2$
 - total: **$\sim 50,000 - 60,000 \text{ m}^2$**
- *plumes can likely be made larger, but cost must be considered

Conclusions

- Based on model results, lower Columbia Gorge tributary confluences could provide effective summer refuge for migrating salmonids, with enhancement.
- Sizes of created refuges in the lower Gorge would be comparable to those of existing mid-Columbia refuges with documented salmonid use.
- Structures are needed to divert mainstem flows. Existing landforms are not enough by themselves.
- Plume characteristics (size and temperature) are highly dynamic due to multiple forcing factors (flows, water temperatures, atmospheric effects)

Next steps

- Simulate different structure types for selected alternatives. Full vs. partial, material types, etc.
- Geomorphic analysis (structure, plume, tributary stability).
- Closer assessment of secondary forcing factors (wind, air temperature, etc.).
- Test model sensitivity (friction, eddy viscosity)
